Nitrogen-containing compounds are a privileged class of molecules, which have applications in medicines, agrochemicals, dyes and materials.¹ As a result, the construction of C–N bonds is an extremely active area of research. Nitrogen-centered radicals are a versatile class of intermediates however, the difficulties associated with their generation have significantly thwarted their use in synthetic chemistry.²

We have accomplished the formation and use of iminyl,³ amidyl⁴ and aminyl⁵ radicals in novel aminofunctionalization reactions through the design of a new class of reactive oximes, hydroxyamides and hydroxylamines. Owing to their redox properties, they could be successfully engaged in hydroamination, amino-functinalization and N-arylation reactions.
